Wisdom is not the product of schooling but the lifelong attempt to acquire it.
- Albert Einstein

High-Functionality Applications
and
User Modeling

Gerhard Fischer
Center for LifeLong Learning & Design (L3D)

Department of Computer Science and Institute of Cognitive Science
University of Colorado, Boulder

Tutorial (December 5, 2000) at OZCHI 2000
High-Functionality Applications

• **high-functionality applications**
  - are used to model parts of existing worlds (and to create new worlds)
  - are complex systems because they serve the needs of large and diverse user populations → hypotheses/fact: "if we ask 100 different people what features they would like to have in a particular application, we will end up with a very large number of features"

• **examples**: (VCRs), Unix, MS-Word, MS-Office, Photoshop, Eudora, Mathematica, ........

• **the design of HFAs must address three problems:**
  - commonly used functionality should not be difficult to learn, use, and remember
  - unknown existing functionality must be accessible or delivered at times when it is needed
  - the unused functionality must not get in the way
Design Challenge: useable **versus** useful → usable **and** useful

"If ease of use was the only valid criterion, people would stick to tricycles and never try bicycles".
Doug Engelbart

Success Story of a High-Functionality Application
——
A Large Hardware Store with Knowledgeable Sales Agents

• empirical study: McGuckin Hardware store in Boulder, Colorado — more than 350,000 different line items

• problem setting and problem solving are intertwined

• queries are articulated incrementally, situations talk back, examples are critical

• to determine the relevance of a found object requires domain knowledge (e.g., “simulation of use” — the plumber story)

• a shared understanding is incrementally achieved between customer and sales agent

• summary: “computer systems have the same functionality as McGuckin, but are operated like K-Mart”
High-Functionality Applications (HFA)

Levels of Users' Knowledge About a System's Information Spaces

(based on numerous empirical investigations)
Functionality and its Relevancy to the Task at Hand in HFAs

Why “Did You Know (DYK)” and “MS Tip of the Day” is of limited success
Expertise in HFAs is an Attribute of a Context, not of a Person
Problems with HFAs

• users do not know about the existence of tools \( (D_4 \not\rightarrow \land D_3) \)

• users do not know how to access tools

• users do not know when to use tools — lack applicability conditions

• users cannot combine, adapt, and modify tools according to their specific needs

• additional complicating factor: in the real world problems are not given but emerge, implying that no precise goals and specifications can be articulated → intertwining of problem framing and problem solving
Entering Unknown Parts of $D_4$ — Opportunity or Problem

• **issues:** a user hits the wrong keys (but the keystrokes get interpreted in $D_4$); the system infers the “wrong” intentions from the users actions — “every wrong answer is the right answer to some other question”

• **problem:** “smart” systems are often guessing wrong (e.g., in MS-Word: AutoCorrect, Tables, Bullets and Numbering, ……)

• **opportunity:** serendipity
Problems with HFAs: Microsoft’s View and Objectives

- some "routine" tasks could be and needed to be automated
- some tasks are used too infrequently by users to make it worthwhile for them to learn how to complete them and complex enough that users would need to relearn how to perform them each time they tried to accomplish the task (main streets and side streets)
- complex tasks may include options that could benefit the users - options that the user might never take advantage of
- users have different levels of expertise and backgrounds and therefore require different levels of support
- tasks supported by software are broad
- users don't want to become technical experts, they just want to get their tasks done
- users don't know about all software features that could help them
- help is insufficient, spread out over the user interface, hard to use, and requires prior knowledge of computer software lingo
- users want tailored help delivered in a friendly and easy to understand manner
How Our Research Addresses the Problems Created by HFAs

- **active help systems** — analyze the behavior of users and infer higher-level goals from low-level operations

- **specification components** — allow users to enrich the description of their tasks

- **critiquing components** — analyze and infer the task at hand; detect and identify the potential for a design information need; present contextualized knowledge for designers

- **increase user and task relevance** by integrating specification component and critiquing components; *generic critics* (defined at design time) → *specific critics* (information only known at use time)

- **create malleable systems** by integrating adaptive and adaptable components
Information Delivery, Contextualization and Intrusiveness
Some Challenging Research Problems for User Modeling

- **identify user goals from low-level interactions**
  - active help systems, data detectors
  - “every wrong answer is the right answer to some other question”

- **integrate different modeling techniques**
  - domain-orientation
  - explicit and implicit
  - give a user specific problems to solve

- **capture the larger (often unarticulated) context and what users are doing** (especially beyond the direct interaction with the computer system)
  - embedded communication
  - ubiquitous computing

- **reduce information overload by making information relevant**
  - to the task at hand
  - to the assumed background knowledge of the users

- **support differential descriptions** (relate new information to information and concepts assumed to be known by the user)
Early Example: Knowledge-Based Help Systems (CHI’85) — Activist (and Passivist)

• **Activist — an active help system** for an EMACS-like editor, deals with two different kinds of suboptimal behavior:
  - the user does not know a complex command and uses “suboptimal” commands to reach a goal (“suboptimal”: main streets and side streets?)
  - the user knows the complex command but does not use the minimal key sequence to issue the command

• similar to a human observer, **Activist handles the following tasks:**
  - recognizes what the user is doing or wants to do
  - evaluates how the user tries to achieve his/her goal
  - constructs a model of the user based on the results of the evaluation task
  - decides (dependent on the information in the model) *when* and *how* to interrupt (tutorial intervention)

• the recognition and evaluation task is delegated to **20 different plan specialists**

interpretive critics
Embedding Critics

Saying the “right” thing
at the “right” time,
in the “right” way

• benefits of embedding critics
  - integrate design environment components
  - allow system to infer the task at hand and user characteristics
  - enable only the most relevant critic rules
  - modify critic rules to reflect task at hand and user characteristics
  - deliver more relevant information
# A Comparison between Adaptive and Adaptable Systems

Adaptation Mechanism to Control Different Critiquing Rule Sets and Different Intervention Strategies

Select Perspective:

Select the standard(s) you want to use when analyzing your design. This allows you to view your design from multiple perspectives. Click on the button to the left to enable the rule set. Click on Argumentation to list all the rules which belong to the selected standard. You can disable and enable individual critic rules within each standard from this overview. To change priority, disable the rule set, then enable it again.

Priority  Enable/Disable Set  Explanation
2  USWEST Rule Set  Argumentation
0  UMUIF Rule Set  Argumentation
0  International Rule Set  Argumentation
1  Consistent with: VM-Residential  Argumentation

Type of Application: Voice Mail

Critique All
Is End-User Modifiability the Answer to HFAs? The message of this section about HFA is that they contain too much unused functionality — at least in the abstract. But on the other hand: there is often not enough functionality for specific problems. As argued at other places in this book, closed systems are inadequate to capture the unanticipated needs of users in the real world. No matter how much designers at design time try to anticipate the needs of users at use time (see Figure<design/usetime>), the effort will fall...
Conclusion

- the challenge is

not only to create more functionality

but: to design usable, useful, learnable, memorizable, applications
